Question 1:

The number of rows in the pattern is represented by the variable rows, which is first initialized to 5. After that, the star pattern is printed using two nested for loops. The inner loop prints i+1 stars in each row while the outside loop iterates from 0 to rows-1 in the first half of the pattern. The inner loop prints i-1 stars in each row while the outer loop iterates from rows down to 1 in steps of -1 in the second part of the pattern.

```

1. Use a python code to display the following star pattern using the for loop

rows = 5

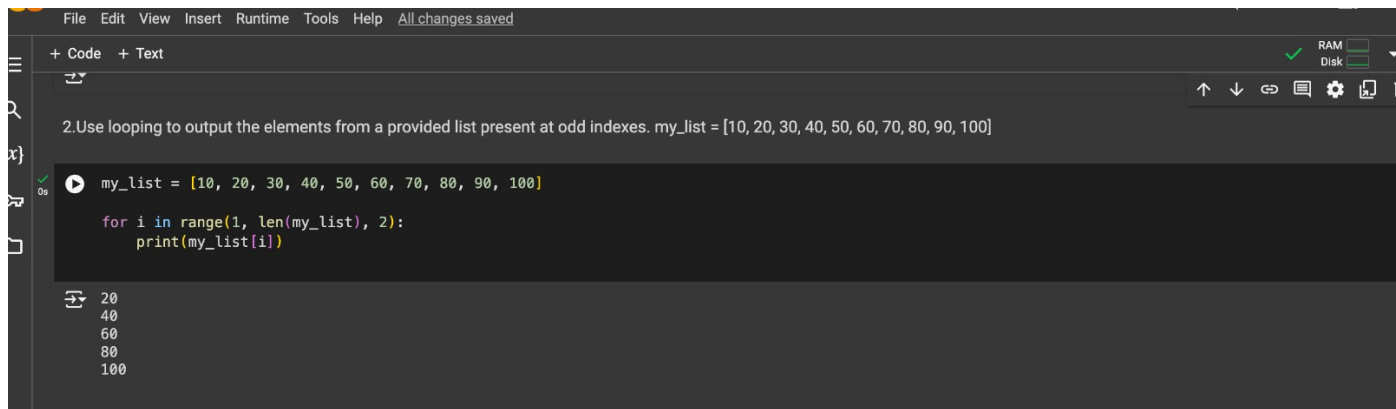

for i in range(0, rows):
    for j in range(0, i + 1):
        print("*", end=' ')
    print("\n")

for i in range(rows, 0, -1):
    for j in range(0, i - 1):
        print("*", end=' ')
    print("\n")

*

* * *
* * * *
* * * * *
* * * *
* * *
* *
*
*
```

Question 2:

The code initializes a list named `my_list` containing integers. It uses a for loop with the `range()` function to iterate over the indices of `my_list`. The loop starts from index 1 because it wants to print elements at odd indices. The loop goes up to `len(my_list)` (the length of the list) with a step of 2 ensuring it only visits odd indices. Inside the loop, it prints the element at the current odd index using `my_list[i]`.

The screenshot shows a code editor with a menu bar (File, Edit, View, Insert, Runtime, Tools, Help) and a status bar (All changes saved). The code editor has tabs for '+ Code' and '+ Text'. The code being executed is:

```
2. Use looping to output the elements from a provided list present at odd indexes. my_list = [10, 20, 30, 40, 50, 60, 70, 80, 90, 100]

my_list = [10, 20, 30, 40, 50, 60, 70, 80, 90, 100]

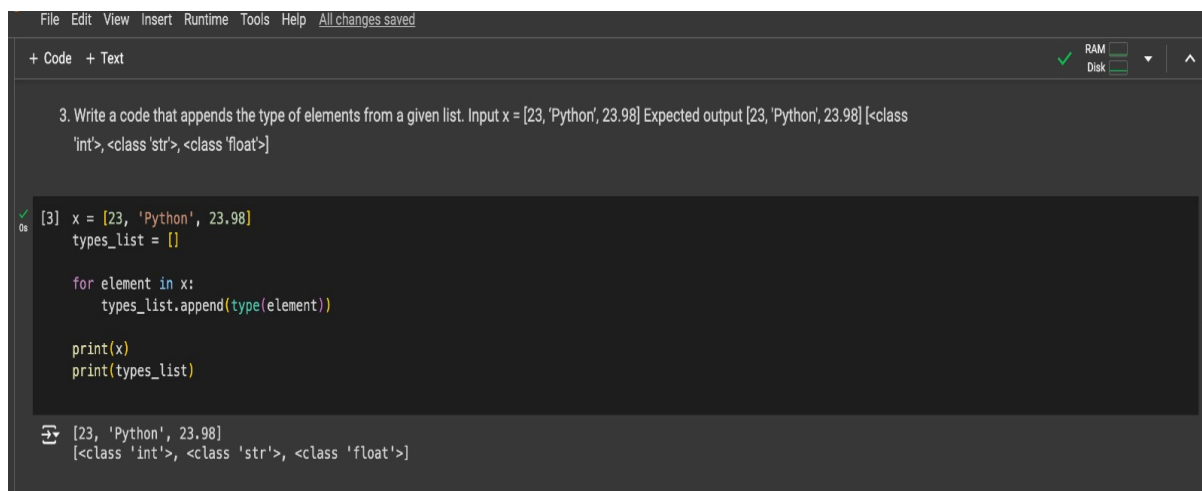

for i in range(1, len(my_list), 2):
    print(my_list[i])
```

The output of the code is displayed in the console:

```
20
40
60
80
100
```

Question 3:

We iterate over each element in the list `x`. For each element, we use the `type()` function to determine its type, and then append that type to the `types_list`. Finally, we print both the original list `x` and the list containing types `types_list`.

The screenshot shows a code editor with a menu bar (File, Edit, View, Insert, Runtime, Tools, Help) and a status bar (All changes saved). The code editor has tabs for '+ Code' and '+ Text'. The code being executed is:

```
3. Write a code that appends the type of elements from a given list. Input x = [23, 'Python', 23.98] Expected output [23, 'Python', 23.98] [<class 'int'>, <class 'str'>, <class 'float'>]

x = [23, 'Python', 23.98]
types_list = []

for element in x:
    types_list.append(type(element))

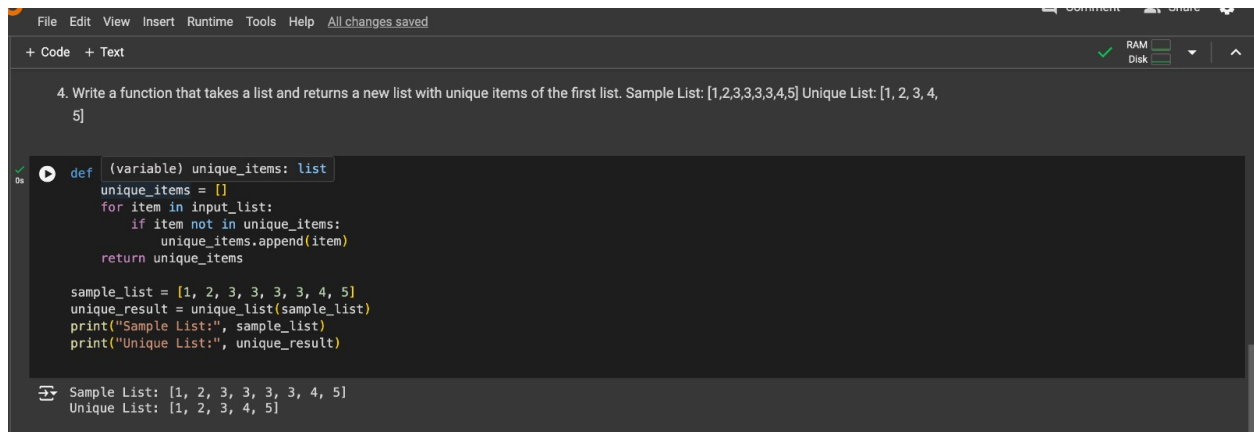

print(x)
print(types_list)
```

The output of the code is displayed in the console:

```
[23, 'Python', 23.98]
[<class 'int'>, <class 'str'>, <class 'float'>]
```

Question 4:

The function `unique_list` takes a list `input_list` as input. It initializes an empty list `unique_items` to store unique elements. It iterates through each element in the input list. For each element, it checks if it's already in the `unique_items` list. If not, it appends it. Finally, it returns the list of unique items.

The screenshot shows a code editor with a dark theme. At the top, there's a menu bar with 'File', 'Edit', 'View', 'Insert', 'Runtime', 'Tools', and 'Help'. Below the menu bar, there's a toolbar with '+ Code' and '+ Text'. The main code area contains the following Python code:

```
4. Write a function that takes a list and returns a new list with unique items of the first list. Sample List: [1,2,3,3,3,4,5] Unique List: [1, 2, 3, 4, 5]

def (variable) unique_items: list
    unique_items = []
    for item in input_list:
        if item not in unique_items:
            unique_items.append(item)
    return unique_items

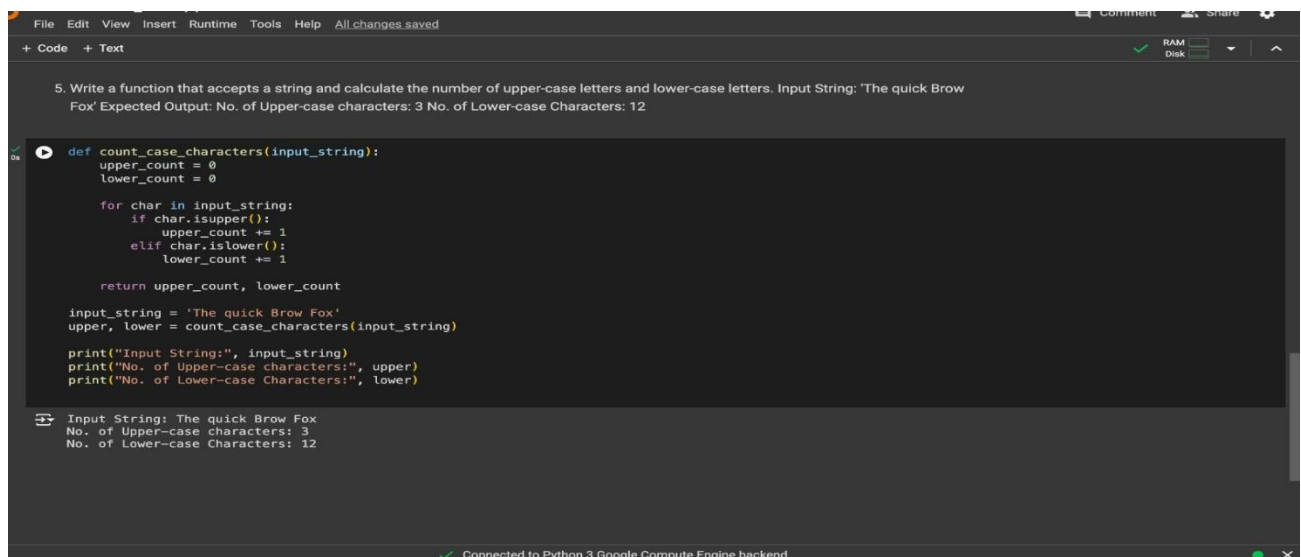

sample_list = [1, 2, 3, 3, 3, 3, 4, 5]
unique_result = unique_list(sample_list)
print("Sample List:", sample_list)
print("Unique List:", unique_result)
```

Below the code, there's a console output showing the results of the execution:

```
Sample List: [1, 2, 3, 3, 3, 3, 4, 5]
Unique List: [1, 2, 3, 4, 5]
```

Question 5:

The function `count_case_characters` accepts a string `input_string` as input. It initializes variables `upper_count` and `lower_count` to store the counts of uppercase and lowercase letters, respectively. It iterates through each character in the input string. For each character, it checks if it's uppercase using the `isupper()` method and increments the `upper_count` if it's true. Similarly, it checks if the character is lowercase using the `islower()` method and increments the `lower_count` if it's true. Finally, it returns the counts of uppercase and lowercase characters.

The screenshot shows a code editor with a dark theme. At the top, there's a menu bar with 'File', 'Edit', 'View', 'Insert', 'Runtime', 'Tools', and 'Help'. Below the menu bar, there's a toolbar with '+ Code' and '+ Text'. The main code area contains the following Python code:

```
5. Write a function that accepts a string and calculate the number of upper-case letters and lower-case letters. Input String: 'The quick Brow Fox' Expected Output: No. of Upper-case characters: 3 No. of Lower-case Characters: 12

def count_case_characters(input_string):
    upper_count = 0
    lower_count = 0

    for char in input_string:
        if char.isupper():
            upper_count += 1
        elif char.islower():
            lower_count += 1

    return upper_count, lower_count

input_string = 'The quick Brow Fox'
upper, lower = count_case_characters(input_string)

print("Input String:", input_string)
print("No. of Upper-case characters:", upper)
print("No. of Lower-case Characters:", lower)
```

Below the code, there's a console output showing the results of the execution:

```
Input String: The quick Brow Fox
No. of Upper-case characters: 3
No. of Lower-case Characters: 12
```

At the bottom of the editor, there's a status bar that says 'Connected to Python 3 Google Compute Engine backend'.
